

How to deploy settings for Basic Parallels Client silently

• Parallels Remote Application Server

Information

The **Basic Windows Client** doesn't store its settings in System registry (as the full Client does) and isn't installed by MSI, so it requires another method for deploying its settings.

If you'd like to deploy settings to **Basic Windows Client**, please do the following:

- 1. Extract the Basic client somewhere on your PC (say C:\RASClient_Basic-x64-17.1.21792\);
- 2. Start **AppServerClient.exe** in that folder;
- 3. When prompted, add a new Connection:

4. Configure its settings like server name, connection mode, and others, **not specifying the username and password** and click **OK**:

5. Click Cancel in the next window:	
6. You will see a new file named mysettings.xml in the fold	ler:

Now you may transfer **mysettings.xml** to another computer and place it in the folder where its Basic Client was extracted. Once the client is started, it will read settings from that file.
